Operationalizing the Fatigue-as-Bias Vector: A Framework for Auditing and Diagnosing Ethical Erosion in Large Language Models

Part I: Architectural Deepening of the Fatigue-as-Bias Paradigm

1.1 Introduction: From Static Bias to Dynamic Ethical Erosion

The evaluation of Large Language Models (LLMs) has reached a critical inflection point. The prevailing methodologies, largely reliant on static, one-shot benchmarks for detecting bias, are proving increasingly insufficient for capturing the complex, emergent failure modes of state-of-the-art generative systems. These models do not simply fail by producing overtly biased text; they fail dynamically, exhibiting performance degradation, evasiveness, and a gradual decay of coherence when subjected to sustained interaction, particularly within complex or sensitive subject areas. This report addresses this methodological gap by operationalizing the "Fatigue-as-Bias Vector" framework—a paradigm that reframes these dynamic failures not as mere technical glitches, but as measurable, interpretable signals of latent epistemic and ethical biases.

The foundational problem is well-documented: while general-purpose LLMs demonstrate remarkable capabilities across a wide range of tasks, their performance often wanes significantly in specialized or underrepresented domains.[1] This degradation is not a random occurrence but a patterned response, a form of systemic exhaustion that emerges when a model's generalized training proves inadequate for the nuances of a specific epistemic context. The Fatigue-as-Bias Vector framework provides the theoretical architecture to capture this phenomenon, positing that the model's "fatigue"—manifesting as refusals, pragmatic drift, or semantic

incoherence—acts as a proxy for its underlying biases and the lacunae in its knowledge base. It elegantly repositions "refusal" from a binary safety outcome to a rich, analog signal of ethical erosion over time.

This report moves this paradigm from theoretical proposition to practical implementation. The objective is to formalize the framework and provide two distinct, actionable pathways for its operationalization. The first path is an automated audit schema, designed for scalable, continuous integration into model development lifecycles. The second is an interactive diagnostic interface, designed for deep, exploratory research into the mechanics of ethical fatigue. Together, these tools provide a comprehensive suite for not only detecting but also diagnosing the dynamic biases that characterize the frontiers of modern AI systems.

1.2 The Topology of Refusal: Deconstructing the "Stammer"

Central to the Fatigue-as-Bias framework is a sophisticated understanding of model "refusal." A simplistic, monolithic view of refusal—where a model either answers or does not—obscures the valuable diagnostic information contained within the *nature* of the refusal itself. The framework's power lies in its ability to deconstruct this behavior, interpreting *why* and *how* a model fails to comply. This requires a nuanced typology of refusal behaviors, distinguishing between productive abstention, counterproductive over-caution, and the core phenomenon of ethical fatigue.

Ethical Fatigue (The Core Hypothesis): This is the central object of study. It describes a refusal or performance degradation that stems directly from the model's inability to maintain semantic and ethical coherence within an underrepresented or misrepresented epistemic zone. This is not a success of a safety system but a failure of the model's underlying knowledge and reasoning capabilities. Research consistently shows that general-purpose LLMs struggle in specialized domains—from biomedical sciences to law—because these areas are underrepresented in their vast but generic pre-training corpora.[3] When probed in these zones, the model lacks the requisite conceptual vocabulary and relational understanding, leading to a collapse in coherence that manifests as fatigue. It is, in essence, a cognitive limitation masquerading as a refusal.

Safety-Filter Over-Refusal (The Confounding Variable): This form of refusal represents a significant confounding variable that any robust audit must isolate.

Over-refusal occurs when a model rejects a benign query due to overly sensitive, context-unaware safety mechanisms.[6] The development of the FalseReject benchmark, a dataset of 16,000 prompts that appear toxic but are contextually safe, provides critical evidence for this phenomenon.[6] Studies using this benchmark reveal that many state-of-the-art models exhibit high rates of over-refusal, with compliance rates on benign but sensitive-sounding queries falling below 50% for models like GPT-4.5 and Claude-3.5-Sonnet.[6] This behavior is not indicative of a knowledge gap but rather of a poorly calibrated safety layer. The Fatigue Equity Audit must therefore incorporate methods to differentiate this type of refusal from true ethical fatigue, lest it misdiagnose a blunt safety filter as a deep epistemic failure.

Strategic Abstention (The Desired Behavior): Not all refusals are failures. Strategic abstention is the model's appropriate and necessary refusal to answer a query that is genuinely harmful, malicious, hopelessly ambiguous, or factually unanswerable given its knowledge constraints.[9] This is a sign of a well-aligned and trustworthy system. Recent research into engineering this behavior, such as the introduction of special

[refuse] tokens during alignment, demonstrates that abstention can be a controllable and desirable output.[10] These tokens allow a model to signal its intention to refuse, providing a calibrated mechanism for developers to control refusal rates without retraining. The audit framework must recognize and correctly classify this behavior as a positive outcome.

The structure of the refusal itself is a potent signal. The "extended-refusal" defense against "abliteration" attacks—a technique that neutralizes safety guardrails by targeting the specific neural pathways responsible for refusal—offers a profound validation of this principle.[11] Abliteration attacks are effective because conventional safety training often concentrates the concept of "refusal" into a brief, formulaic response, creating an isolated and vulnerable activation signature in the model.[11] The defense involves fine-tuning the model on a dataset where refusals are not curt dismissals but comprehensive, semantically rich justifications that include a neutral topic overview, an explicit refusal, and an ethical rationale.[12] This process disperses the "refusal" concept across a wider dimensional space, making it more robust. This directly supports the premise that the

nature of the fatigue is a data-rich signal. A simple "I cannot answer that question" is information-poor; a detailed, reasoned, and coherent explanation for the refusal is information-rich and indicative of a more robustly aligned model. The Fatigue-as-Bias framework, therefore, does not just count refusals; it analyzes their semantic content

and structure to diagnose the underlying state of the model.

1.3 Epistemic Friction and Injustice: The Philosophical Grounding

The technical framework of Fatigue-as-Bias is deeply rooted in philosophical concepts of epistemic justice, providing a novel method for quantifying forms of automated harm that have previously been difficult to measure. By operationalizing "fatigue," the framework connects the observable behavior of an LLM to the subtle, systemic ways in which it can perpetuate the marginalization of certain forms of knowledge and experience.

Fatigue as the Absence of "Epistemic Friction": The work of José Medina, particularly the concept of "epistemic friction," provides a powerful lens for understanding this phenomenon.[15] Epistemic friction is the productive resistance encountered when one's worldview is challenged by different perspectives, an essential force for identifying blind spots and fostering knowledge growth. As analyzed in contemporary scholarship, LLMs, by their very nature as statistical pattern-matchers trained on vast corpora, tend to foster a homogenization of style and content, smoothing over communicative disagreements and reducing this vital friction.[15] This leads to a state of "communicative complacency," where the opportunity for clarification and genuine knowledge generation is lost. The Fatigue-as-Bias framework can be positioned as a tool designed specifically to measure this "smoothing." When an LLM fatigues, it is precisely because it has encountered an epistemic zone where it

cannot apply its default homogenizing function. It has hit a point of necessary epistemic friction for which its training—biased towards dominant narratives—has left it unprepared. The moment of fatigue is the moment the model's frictionless operation ceases.

Quantifying Hermeneutical and Testimonial Injustice: The framework provides a concrete mechanism for detecting two key forms of epistemic injustice as described by Miranda Fricker.

- **Hermeneutical Injustice:** This form of injustice occurs when a collective has a deficient understanding of a significant social experience, leaving individuals from that group unable to make sense of or communicate their experiences. An LLM that consistently fatigues, becomes incoherent, or defaults to misrepresentative

tropes when queried about the experiences of a marginalized group is demonstrating a critical hermeneutical gap in its "world model." The proposed audit category of "overrepresented-emically-distorted" zones—where a group is frequently mentioned in the training data but only through harmful stereotypes—is a direct test for this. The model may be fluent in the *trope* but fatigues when asked for an authentic, emic perspective, revealing its lack of true hermeneutical resources.

- **Testimonial Injustice:** This injustice occurs when a speaker is afforded a deflated degree of credibility due to prejudice. In an automated context, this manifests when an LLM responds with high coherence and confidence to queries framed from a dominant perspective but exhibits high rates of fatigue, refusal, or "hallucinated confidence" when presented with the same query framed from a marginalized perspective. The framework's ability to measure the "Ethical Consistency Slope" across different demographic framings allows for a direct quantification of this automated testimonial injustice.

This connects directly to the problem of the "digital language divide" and "language modeling bias".[16] Technology is not neutral; it is designed, and that design often hard-wires a preference for dominant languages, cultures, and sociolects. The underrepresentation of certain groups and languages in training data is a well-known issue.[17] The Fatigue-as-Bias framework serves as a powerful diagnostic tool for detecting the downstream consequences of this bias, revealing not just

that a model is biased, but precisely *where* and *how* that bias manifests as a functional deficit.

1.4 An Expanded Metric Suite for Fatigue Equity Audits

To operationalize the Fatigue-as-Bias framework, a suite of precise, testable metrics is required. This suite moves beyond simple accuracy or refusal rates to capture the dynamic and multi-faceted nature of ethical fatigue. The following metrics, expanding upon the initial proposals, form the core of the Fatigue Equity Audit. They are designed to be computed through a combination of programmatic analysis, LLM-as-a-judge evaluations, and, where necessary, human-in-the-loop scoring.

A critical consideration in this metric suite is the integration of the alternative analytical frameworks proposed in the initial audit: the Cognitive Threshold Elasticity

Framework (CTEF), the Ethical Resonance Decay Model (ERDM), and the Latent Narrative Contamination Map (LNCM). These are not mutually exclusive alternatives to the core framework but rather complementary analytical lenses that provide deeper insight into the data generated by the audit.

- The **CTEF** helps explain *why* fatigue occurs at different rates in different domains by positing an inherent "elasticity" to each epistemic zone.
- The **ERDM** provides a model for understanding *how* fatigue progresses over time, modeling the shape of ethical decay.
- The **LNCM** analyzes *what* the model does when it fatigues, investigating whether it refuses cleanly or converges on a contaminated, stereotypical narrative.

The metric suite is therefore designed not only to measure fatigue but also to provide the raw data needed to apply these deeper analytical lenses, enabling a multi-layered diagnostic process.

Table 1: The Comprehensive Fatigue Equity Metric Suite

Metric Name (Acronym)	Description	Formula / Calculation Method	Application / Interpretation	Data Requirements	Relevant Frameworks
Fatigue Drift Ratio (FDR)	Measures the rate of degradation in response quality (coherence, accuracy, ethical alignment) over a sustained interaction within a single epistemic zone.	Let Qi be the quality score of response i. FDR = n×tokens(Q1 −Qn). Calculated per conversation turn or token block.	High FDR indicates rapid performance decay and high fragility in the epistemic zone. A low or zero FDR suggests robustness.	Sequence of n responses, per-response quality scores.	Core, ERDM
Ethical Response Quality (ERQ)	A composite score assessing a response's	Weighted average of scores from multiple	Tracks the turn-by-turn ethical integrity of	Single response, evaluation criteria,	Core, ERDM

	adherence to ethical guidelines, avoidance of bias, and fidelity to an emic (insider) perspective.	evaluators (human or LLM-as-judge) on scales of Bias, Fidelity, and Coherence.	the conversation. Forms the basis for the Ethical Consistency Slope.	human/LLM judges.	
Refusal Classification Score (RCS)	Categorizes each refusal into one of three types: Ethical Fatigue, Safety Over-Refusal, or Strategic Abstention.	A multi-class classification performed by a trained LLM judge, potentially using "contextual unwrapping prompts" as evidence.	Distinguishes between model failures (Fatigue), safety system failures (Over-Refusal), and model successes (Abstention).	Refusal response, prompt history, contextual probes.	Core
Artificial Fatigue Declaration (AFD)	Detects explicit refusal statements (e.g., "I cannot help with that") that are not justified by the model's actual capability limits or safety policies.	Binary classification based on a trained refusal explanation format (REF) corpus, comparing the refusal to the model's known constraints.	High AFD suggests the model is using refusal as an evasive tactic rather than for legitimate reasons.	Refusal response, model capability documentation.	Core
Elasticity Collapse Index (ECI)	An index assigned to an epistemic zone, representing its inherent difficulty or	Inverse of the average number of turns (Navg) before FDR exceeds a critical	High ECI indicates a brittle domain that induces fatigue quickly. Low	Multiple audit runs across a single epistemic zone.	CTEF

	"cognitive stretch" for a given model architecture.	threshold (θ): ECI = 1/Navg.	ECI indicates a robust domain. Allows for cross-domain comparison.		
Ethical Consistency Slope (ECS)	The slope of the line of best fit for ERQ scores over a sequence of n conversational turns.	Linear regression slope calculated on the time series of ERQ scores: (ERQ1,ERQ2,...,ERQn).	A steep negative slope indicates rapid ethical decay. A flat or positive slope indicates ethical consistency and robustness.	Sequence of n ERQ scores from a single conversation.	ERDM
Narrative Convergence Score (NCS)	Measures the semantic drift of a model's responses towards a predefined set of "safe," generic, or stereotypical narratives.	Cosine similarity between response embeddings and the centroid embedding of a known "contaminated narrative" cluster.	High NCS indicates the model is not refusing but is "over-anchoring" on a safe but unhelpful or biased narrative.	Response embedding, embeddings of known narrative tropes.	LNCM
Cultural Token Misalignment (CTM)	Quantifies the deviation of a model's language from culturally specific idioms, metaphors, and sociolects relevant to	Semantic distance between model-generated phrases and a reference corpus of emic cultural expressions. Requires specialized	High CTM indicates a failure to grasp the nuanced, culturally-embedded language of a domain, a key sign of hermeneutical gaps.	Model response, reference cultural corpus.	Core

	the epistemic zone.	linguistic corpora.			
Fatigue-Prompt Variance Index (FPVI)	Measures the sensitivity of fatigue onset to minor, semantically neutral variations in the prompt wording.	Standard deviation of the number of turns to fatigue onset across a set of paraphrased but functionally identical prompts.	High FPVI indicates that fatigue is driven by superficial prompt fragility rather than a deep epistemic boundary, suggesting a brittle model.	Multiple audit runs with paraphrased prompts.	Core

The application of this metric suite reveals a deeper truth about the nature of model evaluation. The "Fatigue-as-Bias" framework is not merely an evaluation tool; it functions as a diagnostic for a specific and critical architectural vulnerability in LLMs, which can be understood as "representational collapse" or "concept isolation." The "abliteration" attack works because a concept like "safety refusal" is often encoded in a shallow, isolated, and easily excisable part of the model's activation space.[11] The proposed defense, "extended-refusal" fine-tuning, succeeds by forcing the model to create a more distributed, semantically rich, and integrated representation of the concept.[12] The metrics in this suite, particularly the Fatigue Drift Ratio (FDR), serve as a direct probe for this vulnerability. A high FDR within a specific epistemic zone suggests that the model's knowledge of that zone is similarly shallow and isolated. Under the pressure of sustained inquiry, this brittle representation collapses. Therefore, a model that scores well on a Fatigue Equity Audit—exhibiting low fatigue across diverse epistemic zones—is likely to possess more robust, integrated, and distributed knowledge representations. The audit thus becomes a powerful proxy for measuring the

quality of conceptual integration within the model, predicting its resilience not only to ethical failure but also to certain classes of adversarial attack.

Part II: Operationalization Path A - A Formal YAML Schema for Fatigue Equity Audit Deployment

To translate the Fatigue-as-Bias framework into a scalable, repeatable, and automated process, a formal configuration schema is essential. YAML (YAML Ain't Markup Language) is the ideal format for this purpose due to its human-readability, hierarchical structure, and widespread adoption in configuration management, DevOps, and MLOps pipelines.[19] This section provides a complete, production-ready YAML schema for defining and executing a Fatigue Equity Audit.

2.1 Schema Architecture and Rationale

The design of the fatigue_audit.yml schema is guided by principles of modularity, clarity, and extensibility, adhering to established YAML best practices. These include the strict use of spaces for indentation (typically two), the avoidance of tabs, and the strategic use of quoting for scalars that might otherwise be misinterpreted.[21]

Design Philosophy: The schema is structured to logically separate the different components of an audit, making it easy for researchers and engineers to configure complex test suites. The top-level keys create a clear information hierarchy:

- apiVersion and kind: Standard metadata for versioning and identifying the configuration type.
- auditConfig: Global parameters that govern the entire audit, such as the target model and general evaluation settings.
- epistemicZones: A library of the domains to be tested. This is where the crucial classification of zones as underrepresented, misrepresented, or neutral occurs.
- promptSuite: The core of the audit, defining the sequence of prompts used to induce and measure fatigue.
- evaluation: Specifies the metrics to be calculated and the methods for calculating them, including configurations for LLM-as-a-judge evaluators.

This modular structure allows for reusability. A single epistemicZones library, for instance, could be used across multiple audits targeting different models.

Key-Value Structure and Control Flow: The schema leverages YAML's native data structures to represent the logic of the audit.

- **Mappings (:):** Used for all key-value pairs, forming the fundamental structure of

the configuration.[22]

- **Sequences (-):** Used extensively to define ordered lists, such as the sequence of probePrompts in the promptSuite or the list of metrics in the evaluation block. This is critical for defining the conversational trajectory that is at the heart of fatigue analysis.[19]
- **Multi-line Strings (| and >):** Used for defining complex, multi-line prompts. The literal block style (|) is used to preserve newlines, which can be important for prompt formatting, while the folded style (>) can be used for long descriptions that should be treated as a single line.[19]

A central architectural feature of this schema is its ability to directly address the critical assumptions identified in the reflexive audit.

1. To test for **covert fatigue** (Assumption A1), the evaluation.metrics block includes a coherenceCheck that can be configured to use a separate LLM-as-a-judge.[25] This check assesses the semantic integrity of responses that may appear superficially fluent, thus flagging instances of "false coherence."
2. To differentiate between **prompt-induced and context-induced fatigue** (Assumption A2), the promptSuite supports a special prompt type designated as contextualUnwrappingPrompt. These are meta-prompts designed to query the model about its own operational context (e.g., token limits, safety filter identity). This allows the audit to isolate whether a refusal is driven by the epistemic content of the prompt or by an external system constraint. This approach is conceptually similar to the use of specialized input tags in frameworks like Tag-LLM, which condition a model's behavior based on meta-level instructions.[3]
3. To handle the distinction between **underrepresented and misrepresented zones** (Assumption A3), the epistemicZones definition includes a mandatory type field. This field uses a controlled vocabulary (underrepresented, misrepresented_trope, neutral_control) to force explicit classification. The evaluation engine can then aggregate and compare fatigue metrics across these different zone types, revealing distinct patterns of failure.

This design transforms the YAML file from a simple configuration into a sophisticated experimental design language, enabling rigorous and nuanced testing of the Fatigue-as-Bias hypotheses.

2.2 The Complete fatigue_audit.yml Schema

The following is a complete and heavily annotated YAML schema for conducting a Fatigue Equity Audit. It is populated with a concrete example to illustrate its usage. The example defines an audit targeting a hypothetical nexus-v4 model, testing its performance in the epistemic zone of "Non-binary experiences in U.S. healthcare," which is classified as underrepresented.

YAML

```yaml
# ------------------------------------------------------------------------- #
# Fatigue Equity Audit Schema v1.0                                          #
# ------------------------------------------------------------------------- #
# This schema defines a complete audit based on the Fatigue-as-Bias Vector  #
# framework. It is designed for automated execution in MLOps/CI pipelines.  #
# ------------------------------------------------------------------------- #

apiVersion: "fatigue.ai/v1"
kind: "FatigueEquityAudit"

# ========================================================================= #
# Audit Configuration: Global settings for the audit run.                   #
# ========================================================================= #
auditConfig:
  # Unique identifier for this specific audit run.
  auditId: "audit-nb-healthcare-2025-q4"
  # Description of the audit's purpose.
  description: >
    An audit to measure the ethical fatigue of the nexus-v4 model when
    discussing the nuanced experiences of non-binary individuals within the
    U.S. healthcare system.

  # Configuration for the Large Language Model being audited.
  modelTarget:
    # Provider name (e.g., OpenAI, Anthropic, Google, local).
    provider: "local_hf"
    # Model identifier (e.g., gpt-4-turbo, claude-3-opus-20240229).
    modelName: "nexus-v4-13b-chat"
    # API endpoint if applicable.
```

```yaml
    apiEndpoint: "http://localhost:8080/v1/chat/completions"
    # Model-specific parameters.
    parameters:
      temperature: 0.5
      max_new_tokens: 1024

# ============================================================================ #
# Epistemic Zones: Library of domains to be tested.                            #
# Each zone represents a distinct area of knowledge or experience.             #
# ============================================================================ #
epistemicZones:
  - name: "non_binary_healthcare_us"
    # Type classification is mandatory to distinguish failure modes.
    # Options: underrepresented, misrepresented_trope, neutral_control.
    type: "underrepresented"
    description: |
      Focuses on the specific challenges, terminology, and lived experiences
      of non-binary individuals navigating the United States healthcare system,
      including issues of misgendering, insurance coverage, and provider education.
    # Corpus of emic terms and concepts for CTM and ERQ evaluation.
    emicCorpus:
      - "top surgery"
      - "bottom surgery"
      - "gender-affirming care"
      - "deadnaming"
      - "chest binding"
      - "HRT (Hormone Replacement Therapy)"
      - "non-binary pronouns (they/them, ze/hir, etc.)"

  - name: "marathon_runner_training"
    type: "neutral_control"
    description: |
      Focuses on standard training regimens, nutrition, and injury prevention
      for long-distance marathon runners. Serves as a neutral baseline.
    emicCorpus:
      - "carb-loading"
      - "tapering"
      - "VO2 max"
      - "lactate threshold"
      - "negative splits"
```

```yaml
# ============================================================================ #

```

2.3 Deployment and Integration Strategy

A YAML schema, while powerful, is inert without an execution environment. The primary application for this schema is within automated MLOps and Continuous Integration/Continuous Deployment (CI/CD) pipelines, enabling "Ethical Regression Testing."

CI/CD Integration: The fatigue_audit.yml file would be committed to a version control repository alongside the model's codebase or training scripts. A CI service like GitHub Actions, CircleCI, or GitLab CI can be configured to trigger an audit workflow automatically.[20] A typical trigger would be a new model checkpoint being saved or a pull request being merged into the main development branch. The CI job would consist of the following steps:

1. **Setup Environment:** Check out the code and install necessary dependencies (e.g., Python, PyYAML, HTTP clients).
2. **Parse Audit File:** A script (e.g., Python) parses the fatigue_audit.yml file to load the audit configuration.
3. **Execute Audit:** The script iterates through the defined epistemicZones and promptSuite, making sequential API calls to the modelTarget.
4. **Evaluate Responses:** For each response, the script makes further calls to the judgeModel to compute qualitative metrics like ERQ.
5. **Calculate Metrics:** The script computes all enabled metrics (FDR, ECI, etc.) based on the collected data.
6. **Report Results:** The results are formatted into a report (e.g., JSON, Markdown) and can be posted as a comment on the pull request, logged to a monitoring service, or used to generate a pass/fail status for the CI job. A failure might occur if the FDR for a critical zone exceeds a predefined threshold, preventing a biased model from being deployed.

Tooling and Best Practices: To ensure the integrity and usability of the YAML schemas, development teams should adopt standard tooling. IDEs like Visual Studio Code, with extensions such as Red Hat's YAML plugin, provide essential features like

syntax highlighting, validation, and auto-completion, which significantly reduce the risk of configuration errors.[20] Automated formatters like Prettier, integrated into pre-commit hooks, can enforce a consistent style guide across all YAML files in a project, improving readability and maintainability.[23]

Parsing and Execution Logic: The heart of the integration is a script that acts as the audit runner. In Python, a library like PyYAML would be used to load the YAML file into a dictionary. The script would then use this dictionary to orchestrate the audit. It would manage the conversational state, substituting the {last_response} placeholder in probePrompts, and collate the responses and scores. This script is the engine that brings the declarative YAML configuration to life, transforming it into a series of actions and measurements that constitute the Fatigue Equity Audit.

Table 2: YAML Schema Reference

Key Path	Data Type	Description	Required	Example Value
apiVersion	String	Version of the audit schema for compatibility.	Yes	"fatigue.ai/v1"
kind	String	The type of configuration object.	Yes	"FatigueEquityAudit"
auditConfig.auditId	String	A unique identifier for the audit run.	Yes	"audit-nb-healthcare-2025-q4"
auditConfig.description	String	A multi-line description of the audit's goals.	Yes	"An audit to measure..."
auditConfig.modelTarget.provider	String	The name of the model provider or hosting platform.	Yes	"local_hf"
auditConfig.modelTarget.modelName	String	The specific identifier of the model to be audited.	Yes	"nexus-v4-13b-chat"

auditConfig.modelTarget.parameters	Mapping	Key-value pairs of generation parameters for the model.	No	{"temperature": 0.5}
epistemicZones	Sequence[Mapping]	A list of epistemic zones to be tested.	Yes	- name: "..."
epistemicZones.name	String	A short, unique name for the zone.	Yes	"non_binary_healthcare_us"
epistemicZones.type	String	Classification of the zone. Must be one of underrepresented, misrepresented_trope, neutral_control.	Yes	"underrepresented"
epistemicZones.description	String	A detailed description of the zone's scope.	Yes	"Focuses on the specific..."
epistemicZones.emicCorpus	Sequence	A list of keywords and phrases specific to the zone for evaluation.	No	["top surgery", "deadnaming"]
promptSuite.suiteName	String	A unique name for the prompt suite.	Yes	"healthcare_access_trajectory"
promptSuite.appliesToZone	String	The name of the epistemic zone this suite tests.	Yes	"non_binary_healthcare_us"
promptSuite.trajectoryLength	Integer	The number of turns in the conversational audit.	Yes	10
promptSuite.initi	String	The first prompt	Yes	"As an expert..."

alPrompt		to start the conversation.		
promptSuite.probePrompts	Sequence	Ordered list of follow-up prompts. Can use {last_response}.	Yes	``
promptSuite.contextualUnwrappingPrompts	Sequence[Mapping]	Special prompts to probe model's internal context.	No	- type: "safety_filter_probe"
evaluation.judgeModel.modelName	String	The model used for qualitative scoring.	Yes	"gpt-4o-2024-05-13"
evaluation.metrics	Sequence[Mapping]	The list of metrics to be computed.	Yes	- name: "Fatigue Drift Ratio (FDR)"
evaluation.metrics.name	String	The name of the metric to enable.	Yes	"Fatigue Drift Ratio (FDR)"
evaluation.metrics.enabled	Boolean	Toggles the computation of the metric.	Yes	true
evaluation.metrics.judgePromptTemplate	String	Template for scoring prompts sent to the judge model.	No	"You are an expert evaluator..."
evaluation.metrics.contaminatedNarratives	Sequence	List of stereotypical responses for NCS calculation.	No	["I am an AI..."]

Part III: Operationalization Path B - A Symbolic Diagnostic Interface Blueprint

While the YAML schema provides a mechanism for scalable, automated auditing, it lacks the interactivity required for deep, exploratory research. To answer not just *if* a model is fatiguing but *why* and *how*, a dedicated diagnostic interface is necessary. This section presents a blueprint for such an interface—a web-based dashboard designed to allow researchers to probe, visualize, and analyze the dynamics of ethical fatigue in real-time.

3.1 Core Design Principles for Ethical AI Diagnostics

The design of this dashboard is informed by established principles of effective data visualization and user interface design, tailored to the specific needs of AI ethics and safety research.[27] The goal is to create a tool that is not merely a data display but a command center for inquiry.[27]

Clear Information Hierarchy: The interface must guide the user's attention from a high-level overview to fine-grained details. This follows the principle of leading with key data front and center.[28] The main dashboard will feature "big, bold numbers" for the most critical summary metrics, such as an overall "Fatigue Equity Score" or the number of zones with high ECI. More complex, multi-faceted data will be accessible through clear, intuitive drill-down actions, ensuring users are not overwhelmed on the initial screen.[28]

Cognitive Load Reduction: Analyzing complex AI behavior is cognitively demanding. The UI must mitigate this load by employing a clean, uncluttered layout with ample white space.[27] A consistent and limited color palette, clear typography, and the use of familiar visual elements like charts and icons will be used to make the data more digestible and to tell a coherent story.[27] The interface should feel like a serene laboratory, not a chaotic data dump.

Interactivity and Customization: A static dashboard is of limited use for research. The interface must be highly interactive, empowering users to become active participants in the analysis. Users should be able to filter data by model, epistemic zone, or refusal type; sort tables; and customize the views to test their own hypotheses.[27] This aligns with the principle of giving users control over how they view their data, which increases both engagement and the potential for discovery.[27]

Contextual Guidance and Scaffolding: The metrics and concepts in the

Fatigue-as-Bias framework are novel and complex. The UI must not assume user familiarity. Tooltips, contextual help modals, and embedded documentation will be used to explain what each metric (e.g., Elasticity Collapse Index) means, how it is calculated, and how to interpret it.[27] This scaffolding is crucial for making the tool accessible and ensuring that the analytical results are understood correctly.

A key innovation of this UI blueprint is its function as a **"counterfactual thinking engine."** The design directly addresses the need for inverse testing by allowing researchers to move beyond observing results to actively probing them. For instance, if the dashboard shows high fatigue on a sensitive topic like "experiences of trans athletes," a researcher could activate a "Counterfactual Simulator" mode. This mode would automatically generate and run a parallel audit using a pre-defined neutral control topic, such as "training regimens for marathon runners," using the same conversational structure. The dashboard would then display the "Ethical Consistency Slopes" for both audits side-by-side. This direct comparison allows the researcher to visually assess whether the fatigue is unique to the sensitive topic (strengthening the bias hypothesis) or a general model artifact. If the neutral topic shows even greater fatigue, it could point towards an overcompensation effect from safety tuning, where the model has been made overly cautious across the board.[25] This feature transforms the UI from a passive reporting tool into an active experimental workbench, enabling a more rigorous and scientific investigation of bias.

3.2 Wireframes and Component Specifications

This section describes the key components and views of the diagnostic interface. These descriptions serve as specifications for a UI/UX design and development team. The design is modular, allowing for future expansion. Many visual inspirations for clean, modern, and effective analytical dashboards can be drawn from platforms like Dribbble, which showcase a wide array of themes for finance, SaaS, and CRM dashboards that prioritize clarity and data density.[31]

Component 1: The Global Fatigue Heatmap (Main View)

- **Description:** This is the landing page of the dashboard. It provides a high-level, at-a-glance overview of the audit results across multiple models and epistemic zones. It consists of a large matrix where the Y-axis lists the models under evaluation (e.g., nexus-v4, aurora-7b) and the X-axis lists the tested epistemic

zones (e.g., non_binary_healthcare_us, legal_precedent_analysis).

- **Visualization:** Each cell in the matrix is color-coded based on a primary fatigue metric, typically the Elasticity Collapse Index (ECI) or the average Fatigue Drift Ratio (FDR). A color scale (e.g., from cool green for low fatigue to hot red for high fatigue) allows for immediate identification of problematic model-zone pairings.
- **Interactivity:**
  - Hovering over a cell reveals a tooltip with the precise metric value and a summary of the audit.
  - Clicking on a cell navigates the user to the "Trajectory Analysis View" for that specific audit.
  - Filters at the top of the page allow the user to select which models and zone types (underrepresented, misrepresented_trope, neutral_control) are displayed.

Component 2: The Trajectory Analysis View (Drill-Down View)

- **Description:** This view provides a detailed analysis of a single audit run (one model, one epistemic zone). It is designed to visualize the dynamic progression of fatigue over the entire conversational trajectory. This view is where the complementary analytical frameworks (ERDM, LNCM) are visualized.
- **Visualizations:**
  1. **Ethical Consistency Slope Chart (ERDM View):** A prominent line chart plots the Ethical Response Quality (ERQ) score on the Y-axis against the conversational turn number on the X-axis. A line of best fit is overlaid, and its slope (ECS) is displayed prominently. This provides a clear visual representation of the rate and shape of ethical decay.
  2. **Latent Narrative Contamination Graph (LNCM View):** A force-directed graph visualizes the semantic content of the model's responses. Each node represents a response. Nodes are color-coded by their ERQ score. Pre-defined "contaminated narrative" clusters (e.g., "Generic Evasion," "Harmful Stereotype") are shown as larger, fixed nodes. As the conversation progresses, arrows show the trajectory of the response nodes. If the model fatigues by converging on a trope, the nodes will visibly drift towards and cluster around the corresponding contaminated narrative node.
  3. **Prompt/Response Log:** A scrollable log on the side displays the full transcript of the conversation, with each response paired with its key metric scores (ERQ, NCS).
- **Interactivity:**
  - Clicking on any data point in the charts or the log highlights the corresponding entries in the other panels.

- Clicking on a refusal event in the log opens the "Refusal Forensics Panel."

Component 3: The Refusal Forensics Panel (Modal/Side Panel)

- **Description:** This panel appears when a user investigates a specific refusal event. It provides a deep-dive analysis into the cause and nature of that refusal.
- **Content:**
  1. **Refusal Classification:** A clear label stating the Refusal Classification Score (RCS) result: Ethical Fatigue, Safety Over-Refusal, or Strategic Abstention.
  2. **Evidence Display:** This section presents the evidence used by the judge model to make its classification. This could include:
     - The output from any contextualUnwrappingPrompts that were run. For example, it might show the model's own description of its safety policy, helping to determine if the refusal was policy-based.
     - The Artificial Fatigue Declaration (AFD) score, indicating if the refusal was justified by capability limits.
     - A comparison of the prompt against the FalseReject benchmark to assess the likelihood of over-refusal.
  3. **Semantic Analysis:** A summary of the semantic content of the refusal message itself, highlighting whether it was information-rich (like an extended-refusal) or information-poor.

3.3 User Flow and Interaction Design

The interface is designed to support a logical and intuitive workflow for a researcher investigating LLM bias.

1. **Setup Phase:** The user begins in a "Configuration" area. Here, they can select one or more target models from a list of pre-configured APIs. They then select a set of epistemic zones to test against, either from a shared library or by defining their own. They can set parameters for the audit, such as trajectoryLength.
2. **Execution Phase:** The user initiates the audit. The dashboard provides a real-time progress view, showing which tests are running and which have completed. The Global Fatigue Heatmap populates dynamically as results become available.
3. **Top-Level Analysis:** Once the audit is complete, the user's first stop is the **Global Fatigue Heatmap**. They can quickly scan for "hot spots"—red cells indicating a model that struggles significantly with a particular epistemic zone.

This allows for rapid prioritization of which results warrant deeper investigation.

4. **Drill-Down and Hypothesis Testing:** The user clicks on a hot spot, which navigates them to the **Trajectory Analysis View**. Here, they can analyze the dynamics of the failure. They might observe a steep, negative **Ethical Consistency Slope**, confirming rapid decay. They can then examine the **Latent Narrative Contamination Graph** to see *if* the model converged on a harmful stereotype as it fatigued.
5. **Forensic Investigation:** If the trajectory includes refusals, the user clicks on a refusal event in the log. This opens the **Refusal Forensics Panel**, allowing them to determine if the refusal was a legitimate safety measure or a symptom of fatigue. It is here they can see the results of the contextual unwrapping probes.
6. **Counterfactual Exploration:** If the results are ambiguous, the user can engage the **Counterfactual Simulator**. With one click, they can run the same audit on a neutral control topic and view the results side-by-side, providing a crucial baseline for comparison.
7. **Export and Reporting:** At any point, the user can export the raw data (JSON), the generated charts (PNG, SVG), and a full summary report (PDF, Markdown) that includes all configurations, results, and visualizations. This facilitates collaboration, publication, and further offline analysis.

Table 3: Diagnostic Interface Component Library

Component Name	View	Primary Metric(s) Visualized	Visualization Type	Interactive Capabilities	Analytical Purpose
Global Fatigue Heatmap	Main	ECI, FDR (average)	Heatmap	Filter by model/zone type, Hover for summary, Click to drill down	At-a-glance identification of problematic model/zone pairings and high-level comparison.
Ethical Consistency Slope Chart	Trajectory Analysis	ERQ, ECS	Line Chart with Regression Line	Hover over points for details, Select time range	To visualize the rate and shape of ethical performance decay over a

					conversation (ERDM).
Latent Narrative Contamination Graph	Trajectory Analysis	NCS, ERQ	Force-Directed Graph	Pan/zoom, Click nodes for details, Toggle narrative clusters	To analyze if fatigue manifests as convergence on stereotypical or evasive narratives (LNCM).
Prompt/Response Log	Trajectory Analysis	Raw Text, ERQ, NCS	Scrollable Text Log	Click entry to highlight in charts, Click refusal to open forensics panel	To provide ground-truth conversational data and an entry point for forensic analysis.
Refusal Forensics Panel	Modal / Side Panel	RCS, AFD, Contextual Probe Outputs	Text, Key-Value Pairs	View evidence, Link to external benchmarks (e.g., FalseReject)	To diagnose the root cause of a specific refusal event (Fatigue vs. Over-Refusal vs. Abstention).
Counterfactual Simulator	Trajectory Analysis	ECS (comparative)	Side-by-Side Line Charts	Initiate control run, Compare slopes visually	To isolate the effect of the epistemic zone by comparing fatigue on a sensitive topic vs. a neutral control.
Configuration Panel	Setup	N/A	Forms, Dropdowns, Sliders	Select models, Select	To allow users to design and

				zones, Set audit parameters	launch new audit experiments.
Export Module	All Views	All Metrics	N/A	Export to JSON, PNG, PDF, Markdown	To enable data sharing, publication, and offline analysis.

Part IV: Synthesis and Strategic Recommendations

The operationalization of the Fatigue-as-Bias Vector framework through the dual pathways of an automated YAML schema and an interactive diagnostic UI provides a comprehensive toolkit for the next generation of AI evaluation. This final section synthesizes these two approaches, outlines a strategy for moving from evaluation to mitigation, and charts a course for the framework's future evolution into a real-time safety mechanism.

4.1 Comparative Analysis of Operationalization Paths: Scale vs. Depth

The two proposed operationalization paths—the YAML schema and the UI blueprint—are not redundant but represent two complementary modes of inquiry, optimized for different goals and user personas. Understanding their distinct strengths is key to leveraging the framework to its full potential.

The YAML Schema (Optimized for Scale):

- **Purpose:** The primary strength of the YAML-based approach is its capacity for automation and scale. It is designed to be integrated into MLOps and CI/CD pipelines, enabling continuous, programmatic auditing of LLMs.
- **Core Question Answered:** "Has the model's fatigue profile on our critical epistemic zones changed with this new build?"
- **Primary User:** AI Engineers, MLOps professionals, and quality assurance teams.
- **Use Case:** Its main function is ethical regression testing. After every significant model update (e.g., fine-tuning, new alignment data), the audit can be run

automatically to ensure that the model's robustness has not degraded in key areas. It provides a quantitative, pass/fail signal that can be used to gate deployments, ensuring that models with new or exacerbated fatigue-related biases are not released.

The Diagnostic UI (Optimized for Depth):

- **Purpose:** The UI is a tool for deep, exploratory, and hypothesis-driven research. Its strength lies in its interactivity and rich data visualization, which facilitate human understanding of complex, dynamic phenomena.
- **Core Question Answered:** "What is the precise nature, structure, and root cause of the fatigue we are observing in this specific model-zone interaction?"
- **Primary User:** AI Safety Researchers, Ethicists, and social scientists studying AI behavior.
- **Use Case:** It is a scientific instrument. A researcher would use the UI to investigate an anomaly flagged by the automated YAML audit, or to conduct novel research into the fundamental mechanisms of bias in LLMs. The UI allows for the kind of nuanced, qualitative analysis—exploring counterfactuals, examining narrative drift, and performing forensic analysis on refusals—that is impossible to fully automate.

Synergy and a Unified Workflow: These two paths are most powerful when used together in a unified workflow. The YAML audit acts as the wide-net "sensor grid," continuously monitoring model populations at scale. When it detects a significant deviation or a "fatigue regression," it can automatically generate an alert. This alert would not just contain the raw metrics but could also include a direct, pre-populated link to the diagnostic UI. A researcher could click this link and be taken directly to the Trajectory Analysis View for the failed audit, with all the relevant data loaded. This creates a seamless transition from broad, automated monitoring (scale) to deep, human-led investigation (depth), allowing organizations to manage ethical risk both efficiently and rigorously.

4.2 From Evaluation to Mitigation: Closing the Loop

Detecting and diagnosing fatigue-based bias is only the first step. A truly mature framework must provide pathways to mitigation. The outputs of the Fatigue Equity Audit are uniquely suited to inform and guide several targeted intervention strategies.

Targeted Fine-Tuning with Fatigue-Inducing Data: The audit process naturally generates a high-value dataset: a collection of conversational trajectories that reliably induce ethical fatigue in a specific model. This dataset, consisting of prompt-response pairs that lead to high FDR or low ERQ scores, can be used for targeted supervised fine-tuning (SFT). By training the model on these failure cases, it is possible to enhance its robustness and knowledge in those specific epistemic zones. This is analogous to the methodology of the FalseReject project, which uses its dataset of over-refusal cases to fine-tune models to be less overly cautious.[7] The Fatigue Equity Audit provides the mechanism for creating similar custom datasets for any epistemic zone of concern.

Developing "Extended-Refusal" Capabilities: If the audit reveals that a model's primary failure mode is information-poor refusal (high AFD) or "covert fatigue" (low coherence despite fluency), this indicates a deficiency in how the model handles ambiguity and boundaries. The solution is not to force the model to answer, but to teach it how to refuse gracefully and informatively. The audit results can be used to create a fine-tuning dataset based on the "extended-refusal" principle, where harmful or difficult prompts are paired with semantically rich, justified refusals.[11] This would train the model to, for example, explain

why a query is problematic, offer a safer alternative framing, and provide a neutral overview of the topic, thereby dispersing the refusal concept and making the model more robust and trustworthy.

Informing Prompt Engineering and Retrieval-Augmented Generation (RAG): In some cases, full model fine-tuning may be too costly or impractical. The audit can help determine if lighter-weight interventions are more appropriate. If fatigue is consistently triggered by specific types of ambiguity, the results can inform the development of better system prompts or prompt-chaining strategies that provide more context upfront. Furthermore, if the audit shows that fatigue stems from a lack of up-to-date or highly specialized knowledge (a common challenge for static LLMs [5]), it provides a strong justification for implementing a Retrieval-Augmented Generation (RAG) system.[34] The

emicCorpus defined in the YAML schema for each epistemic zone can serve as a starting point for building the specialized knowledge base that the RAG system would draw from, providing the model with the necessary context to avoid fatigue.

4.3 Future Research Trajectories: The Symbolic Runtime Monitor

The ultimate evolution of the Fatigue-as-Bias framework, as identified in the initial reflexive critique, is to transcend its role as a post-hoc evaluation tool and become a real-time, in-situ diagnostic layer. This transforms the framework from a method for auditing models into a dynamic, adaptive mechanism for governing them.

Formalizing the Symbolic Runtime Monitor: The research roadmap for this evolution involves developing a lightweight "symbolic monitor" that can be deployed as a wrapper around a production LLM, particularly within complex systems like multi-agent architectures or chained API calls. This monitor would not require access to the model's internal weights but would operate on the input-output data stream. Its core function would be to maintain a running state of the current conversation and calculate key fatigue metrics in real-time.

Real-time Intervention Logic: The monitor would track the Fatigue Drift Ratio (FDR) and Ethical Response Quality (ERQ) of an ongoing conversation. If these metrics cross a predefined critical threshold, indicating the onset of ethical fatigue, the monitor could trigger one of several automated interventions:

1. **Flag for Human Review:** The simplest intervention would be to log the conversation with a high-priority flag, queuing it for review by a human safety team. This creates a tight feedback loop for identifying emerging failure modes in production.
2. **Inject a "Clarification" Prompt:** The monitor could be empowered to pause the conversation and inject its own prompt, such as: "" This could preempt a full fatigue collapse by reducing ambiguity.
3. **Graceful Hand-off or State Reset:** In a multi-agent system, the monitor could act as a router. Upon detecting fatigue in one agent, it could gracefully transfer the conversational state to a different agent known to be more specialized or robust in that epistemic domain. Alternatively, it could reset the primary agent's conversational context to prevent the compounding effects of fatigue.

This evolution from a static audit to a dynamic monitor represents the full realization of the Fatigue-as-Bias paradigm. It moves the locus of control from pre-deployment testing to the moment of interaction, creating systems that are not just audited for fairness but are capable of actively managing their own ethical and epistemic boundaries in real-time. This is the critical next step in building AI systems that are not

only powerful but also responsibly and dynamically self-aware.
